SALES ANALYTICS

StyleSense is a growing clothing retail company that sells Men's, Women's, and Kids' clothing across Physical stores and Online channels. Like many retail businesses today, StyleSense faces growing competition from large e-commerce platforms and needs to make smarter, data-driven decisions to stay profitable.

Business Problem

Despite consistent sales, StyleSense's:

- Profit margins are unclear – cost of goods, payroll, rent, and marketing all eat into revenue.
- Seasonality is not being planned for – winter and summer products go out of stock or sit unsold.
- Promotions and discounts are used freely – but no one knows if they're actually generating profit.
- Customer segments are not being leveraged – VIP customers may be leaving due to lack of retention programs.
- Online vs physical performance is unknown – marketing spend may be mis-allocated.

Project Objective

This project analyzes 18 months (Jan 2024 – Jun 2025) of sales, customer, inventory, and expense data to:

- Understand what has been selling and who is buying (Descriptive).
- Diagnose why performance is the way it is (Diagnostic).
- Predict future revenue trends (Predictive).
- Recommend clear actions management can take to improve ROI (Prescriptive).

Data Understanding

- clothing_sales.csv (10,000 rows)- every transaction: product, channel, price, discount, profit.
- clothing_customers.csv (200 rows)- customer profiles: demographics, segments, purchase history.
- clothing_expenses.csv (1,300 rows)- business costs by category (rent, payroll, COGS, marketing).
- clothing_inventory.csv (13,600 rows)- daily stock levels per product with reorder triggers.
- clothing_products.csv (25 rows)- product master list with base price and cost.

In [1]:
```python
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.ticker as mticker
import seaborn as sns
from sklearn.linear_model import LinearRegression
from sklearn.metrics import r2_score, mean_absolute_error
import warnings

warnings.filterwarnings('ignore')
```

In [2]:
```python
# Chart styling
sns.set_theme(style="whitegrid")
plt.rcParams['figure.dpi'] = 100
plt.rcParams['font.size'] = 10

BLUE   = '#3498DB'
GREEN  = '#27AE60'
RED    = '#E74C3C'
ORANGE = '#E67E22'
PURPLE = '#8E44AD'
GOLD   = '#F39C12'
TEAL   = '#1ABC9C'
GREY   = '#95A5A6'
```

Libraries Used

- pandas & numpy — data manipulation and numerical operations
- matplotlib & seaborn — visualisation (used later in EDA)
- sklearn — LinearRegression for the predictive analysis phase
- warnings.filterwarnings('ignore') — suppresses pandas version warnings that don't affect results but clutter output

In [3]:
```python
# Load all five datasets
sales     = pd.read_csv('clothing_sales.csv')
customers = pd.read_csv('clothing_customers.csv')
expenses  = pd.read_csv('clothing_expenses.csv')
inventory = pd.read_csv('clothing_inventory.csv')
products  = pd.read_csv('clothing_products.csv')
```

In [4]:
```
print(f'  Sales rows:      {len(sales):,}')
print(f'  Customer rows:   {len(customers):,}')
print(f'  Expense rows:    {len(expenses):,}')
print(f'  Inventory rows:  {len(inventory):,}')
print(f'  Product rows:    {len(products):,}')
```

```
  Sales rows:      10,039
  Customer rows:   200
  Expense rows:    1,322
  Inventory rows:  13,675
  Product rows:    25
```

In [5]:
```
#Examine sales data structure
#Looking at the last few rows gives me a sense of: what columns exist,data types (dates, numbers, categories),data qu
#and the most recent transactions (end of June 2025)
sales.tail()
```

Out[5]:

	sale_id	date	store_channel	payment_method	product_id	product_name	category	sub_category	quantity_sold	unit_

dtype: int64
```

There are :

- 5 missing payment_methods
- 101 missing customer_ids

In [7]:
```
#check for nulls in sale_id column
sales.sale_id.isnull().sum()
```

Out[7]:
```
np.int64(0)
```

In [8]:
```
#check for duplicates in sale_id column
sales['sale_id'].duplicated().sum()
```

Out[8]:
```
np.int64(50)
```

- We used keep='first' (not keep=False) because we want to KEEP one copy of each transaction. keep=False would drop ALL copies, losing the sale entirely. Since the duplicate rows are byte-for-byte identical (same date, customer, amount), this is clearly a data export bug.

In [9]:
```python
# See the duplicate rows
dupes = sales[sales['sale_id'].duplicated(keep=False)].sort_values('sale_id')
print(dupes[['sale_id', 'date', 'customer_id', 'product_id', 'quantity_sold', 'total_sale']].head(20))
```

```
      sale_id        date customer_id product_id  quantity_sold  total_sale

```

- The duplicates appear to be exact duplicates,suggesting a system glitch during data export. So I remove duplicates and I keep='first' to preserve one copy of each transaction. This reduces my dataset from 10,039 to 9,989 rows - a 50-row reduction.

In [10]:
```python
# drop duplicates
sales = sales.drop_duplicates(subset='sale_id', keep='first')
print(sales.shape)
```

```
(9989, 18)
```

In [11]:
```python
#check customer_id column
sales.customer_id
```

Out[11]:
```

3    1266
0    1244
1    1244
2    1236
Name: count, dtype: int64
```

- All days have sales, but weekends (5,6) have highest volume. This makes sense for retail and validates data quality.

In [22]:
```
sales[sales['date'] == '']
```

Out[22]:

sale_id	date	store_channel	payment_method	product_id	product_name	category	sub_category	quantity_sold	unit_price

In [23]:
```
#Analyze discount patterns
sales['discount_pct'].value_counts()
```

Out[23]:
```
discount_pct
0     4489
5     2189
10    1829
15    1127
20     355
Name: count, dtype: int64
```

- Discounts are in 5% increments (0,5,10,15,20%).
- This suggests standardized promotions rather than arbitrary discounts.
- 0% discounts (4,489 transactions) might be full-price sales or non-promotional items.

Validate and correct financial calculations

In [24]:
```
# Check if discount was calculated per unit instead of total
sales['discount_check_unit'] = (sales['unit_price'] * sales['discount_pct'] / 100).round(2)
sales[sales['discount_check_unit'] != sales['discount_amount']][['unit_price', 'quantity_sold', 'discount_pct', 'disc
```

```

Recalculate financial metrics

WHY we recalculate instead of trusting the raw values:

- Cell 24 showed discount_amount was calculated per UNIT, not per total.
- Example: qty=3, price=34.99, disc=10% → raw value was 3.50 (per unit) but it should be 10.50 (3 units × 34.99 × 10%). We recalculate all three derived columns from source values to ensure internal consistency across 9,989 rows.

In [26]:
```
sales['discount_amount'] = (sales['unit_price'] * sales['quantity_sold'] * sales['discount_pct'] / 100).round(2)
```

In [27]:
```
sales['total_sale'] = (sales['unit_price'] * sales['quantity_sold'] - sales['discount_amount']).round(2)
sales['gross_profit'] = (sales['total_sale'] - sales['cost_total']).round(2)
```

In [28]:
```
# Referential integrity: cross-check unit_price in sales against base_price in products.
# Expected: unit_price == base_price * (1 - discount_pct/100) for every transaction.
# A mismatch means a product was sold at an unapproved or incorrectly recorded price.
sales_price_check = sales.merge(products[['product_id', 'base_price']], on='product_id', how='left')
sales_price_check['expected_unit_price'] = (
    sales_price_check['base_price'] * (1 - sales_price_check['discount_pct'] / 100)
).round(2)

```
#Handle missing payment methods
sales.loc[sales['payment_method'].isna(), 'payment_method'] = 'Unknown'
```

In [34]:
```
#Handle missing customer_ids
# We do NOT drop these rows because they still contain valid
# revenue and product data that matters for sales analysis.
sales.loc[sales['customer_id'].isna(), 'customer_id'] = 'Guest'
```

There are 101 missing values in customer_id column and could mean:

- Walk-in customers not in loyalty program.
- Online guest checkouts.
- Data entry errors.

So filling with 'Guest' category lets me analyze these separately without losing sales data.

std	13.325458	27.834274	1021.145301	7.305397	NaN	NaN	17.541688

The summary statistics indicate that most numerical variables fall within reasonable and expected ranges. The only anomaly observed is in the age column, where the minimum (0) and maximum (145) values are unrealistic and require cleaning. Other metrics such as total items purchased, total spent, number of orders, and average order value show consistent distributions with no negative or extreme values.

In [49]:

```
customers[(customers['age'] < 18) | (customers['age'] > 100)][ ['customer_id', 'name', 'age']]
```

Out[49]:

	customer_id	name	age
79	C080	Jacob Clark	0
116	C117	Mark Green	145

- The age column has a maximum value of 145 and a minimum value of 0, which are unrealistic and likely the result of data entry or system errors. Since these values do not represent valid customers, I will treat them as invalid observations rather than true

outliers. To maintain data integrity and avoid distorting any age-based sales insights, these values will be replaced with missing (NaN) values instead of being imputed.

In [50]:
```
# We use pd.NA (not np.nan) because 'age' is an integer column.
# pd.NA is the integer-compatible missing value in pandas.
# np.nan would force the column to float64.
customers.loc[(customers['age'] < 18) | (customers['age'] > 100), 'age'] = pd.NA
```

In [51]:
```
# We create age groups because raw age is too granular for
# segment-level analysis. Groups align with standard retail
# demographic brackets (Gen Z, Millennials, Gen X, Boomers).
# Invalid ages (0, 145) are captured as 'Unknown' instead of
# raising an error, which keeps the pipeline robust.
def get_age_group(age):

```

Out[92]:
```
np.float64(1033.77375)
```

In [93]:
```
# Flag potential outliers
# IQR flags 124 rows as 'outliers', but context matters here.
# Rent ($3,500) is a fixed monthly cost — legitimately large.
# COGS spikes on high-sales days — these are the BEST days.
# Applying IQR naively would remove our most important data points.
# Rule: always investigate outliers BEFORE deciding to remove them.
outliers = expenses[(expenses['amount'] < lower_bound) |
                    (expenses['amount'] > upper_bound)]

print(f"Potential outliers: {len(outliers)}")
print(outliers[['date', 'category', 'amount', 'notes']].head())
```

```
Potential outliers: 124
         date            category  amount                     notes
0  2024-01-01                Rent  3500.0        Monthly store rent
6  2024-01-02  Cost of Goods Sold  1424.5                Daily COGS
8  2024-01-03  Cost of Goods Sold  1461.0                Daily COGS
12 2024-01-05             Payroll  2498.5  Weekly payroll - 4 staff
13 2024-01-05  Cost of Goods Sold  1223.5                Daily COGS
```

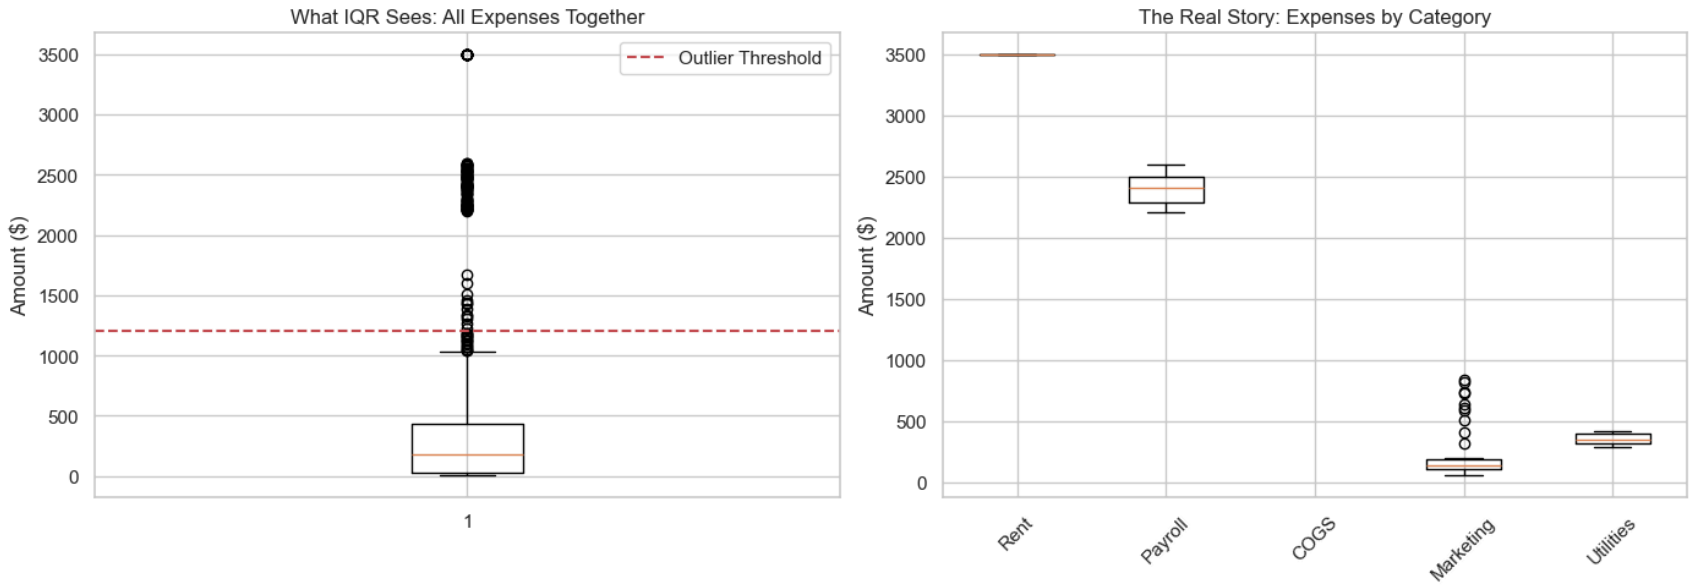
In [94]:

```python
# Visualize outliers
fig, axes = plt.subplots(1, 2, figsize=(14, 5))

# Plot 1: All expenses together
axes[0].boxplot(expenses['amount'])
axes[0].set_title('What IQR Sees: All Expenses Together')
axes[0].set_ylabel('Amount ($)')
axes[0].axhline(y=1200, color='r', linestyle='--', label='Outlier Threshold')
axes[0].legend()

# Plot 2: Expenses by category
categories = ['Rent', 'Payroll', 'COGS', 'Marketing', 'Utilities']
data_to_plot = [expenses[expenses['category'] == cat]['amount'] for cat in categories]
axes[1].boxplot(data_to_plot, labels=categories)
axes[1].set_title('The Real Story: Expenses by Category')
axes[1].set_ylabel('Amount ($)')
axes[1].tick_params(axis='x', rotation=45)

plt.tight_layout()
plt.show()
```



- The 'outliers' aren't errors, they're actually signs of healthy business activity. High COGS days represent our busiest sales periods, rent shows our stable store footprint, and payroll reflects our commitment to staffing during peak times. Removing these would hide the true story of our business performance.

Thus, I'll retain all the otlier values in the dataset for accurate analysis.

Data Cleaning Validation Summary

All five datasets are cleaned and ready for EDA.

Dataset	Issue Found	Fix Applied
Sales	`unit_price` not cross-checked against product catalogue	Merged with products; confirmed all prices match `base_price × (1 - discount_pct)`
Sales	Returned rows carried positive `gross_profit`	Added `net_profit` column (`= 0` for returns); `gross_profit` preserved for margin analysis
Customers	`'New'` segment customers have 29–61 orders	Added `derived_segment` (behaviour-based) alongside original registration-based `segment`

Dataset	Issue Found	Fix Applied
Expenses	Date coverage and fixed-cost completeness not verified	Confirmed Jan 2024 – Jun 2025 (18 months); all fixed-cost categories present every month
Inventory	Near-stockout frequency never quantified	Counted near-stockout events per product; reorder system confirmed functioning

Output files: `sales_clean_data.csv` · `customers_clean_data.csv` · `products_clean_data.csv` · `expenses_clean_data.csv` · `inventory_clean_data.csv`
